ISO 15529:2010(E)

Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO 15529 was prepared by Technical Committee ISO/TC 172, *Optics and photonics*, Subcommittee SC 1, *Fundamental standards*.

This third edition cancels and replaces the second edition (ISO 15529:2007) which has undergone a minor revision to include measurement and test procedures for aliasing of sampled imaging systems.

Introduction

One of the most important criteria for describing the performance of an imaging system or device is its MTF. ISO 9334 covers the conditions to be satisfied by an image system for the MTF concept. These conditions require that the imaging system be linear and isoplanatic.

For a system to be isoplanatic, the image of a point object (i.e. the point spread function) must be independent of its position in the object plane to within a specified accuracy. There are types of imaging systems where this condition does not strictly apply. These are systems where the image is generated by sampling the intensity distribution in the object at a number of discrete points, or lines, rather than at a continuum of points.

Examples of such devices or systems are: fibre optic face plates, coherent fibre bundles, cameras that use detector arrays such as CCD arrays, line scan systems such as thermal imagers (for the direction perpendicular to the lines), etc.

If one attempts to determine the MTF of this type of system by measuring the line spread function of a static narrow line object and calculating the modulus of the Fourier transform, one finds that the resulting MTF curve depends critically on the exact position and orientation of the line object relative to the array of sampling points (see Annex A).

This International Standard specifies an “MTF” for such systems and outlines a number of suitable measurement techniques. The specified MTF satisfies the following important criteria:

- the MTF is descriptive of the quality of the system as an image-forming device;
- it has a unique value that is independent of the measuring equipment (i.e. the effect of slit object widths, etc., can be de-convolved from the measured value);
- the MTF can, in principle, be used to calculate the intensity distribution in the image of a given object, although the procedure does not follow the same rules as it does for a non-sampled imaging system.

This International Standard also specifies MTFs for the sub-units, or imaging stages, which make up such a system. These also satisfy the above criteria.

A very important aspect of sampled imaging systems is the “aliasing” that can be associated with them. The importance of this is that it allows spatial frequency components higher than the Nyquist frequency to be reproduced in the final image as spurious low frequency components. This gives rise to artefacts in the final image that can be considered as a form of noise. The extent to which this type of noise is objectionable will depend on the characteristics of the image being sampled. For example, images with regular patterns at spatial frequencies higher than the Nyquist frequency (e.g. the woven texture on clothing) can produce very visible fringe patterns in the final image, usually referred to as moiré fringes. These are unacceptable in most applications if they have sufficient contrast to be visible to the observer. Even in the absence of regular patterns, aliasing will produce noise-like patterns that can degrade an image.

A quantitative measure of aliasing can be obtained from MTF measurements made under specified conditions. This International Standard defines such measures and describes the conditions of measurement.

Optics and photonics — Optical transfer function — Principles of measurement of modulation transfer function (MTF) of sampled imaging systems

1 Scope

This International Standard specifies the principal MTFs associated with a sampled imaging system, together with related terms, and outlines a number of suitable techniques for measuring these MTFs. It also defines a measure for the “aliasing” related to imaging with such systems.

This International Standard is particularly relevant to electronic imaging devices such as digital still and video cameras and the detector arrays they embody.

Although a number of MTF measurement techniques are described, the intention is not to exclude other techniques, provided they measure the correct parameter and satisfy the general definitions and guidelines for MTF measurement as set out in ISO 9334 and ISO 9335. The use of a measurement of the edge spread function, rather than the line spread function (LSF), is noted in particular as an alternative starting point for determining the OTF/MTF of an imaging system.

2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 9334, *Optics and photonics — Optical transfer function — Definitions and mathematical relationships*

ISO 9335, *Optics and photonics — Optical transfer function — Principles and procedures of measurement*

ISO 11421, *Optics and optical instruments — Accuracy of optical transfer function (OTF) measurement*

3 Terms, definitions and symbols

3.1 Terms and definitions

For the purposes of this document the terms and definitions given in ISO 9334 and the following apply.

3.1.1

sampled imaging system

imaging system or device, where the image is generated by sampling the object at an array of discrete points, or along a set of discrete lines, rather than a continuum of points

NOTE 1 The sampling at each point is done using a finite size sampling aperture or area.

NOTE 2 For many devices “the object” is actually an image produced by a lens or other imaging system (e.g. when the device is a detector array).

ISO 15529:2010(E)

3.1.2

sampling period

a

physical distance between sampling points or sampling lines

NOTE Sampling is usually by means of a uniform array of points or lines. The sampling period may be different in two orthogonal directions.

3.1.3

Nyquist limit

maximum spatial frequency of sinewave that the system can generate in the image, equal to $1/(2a)$

NOTE See also 3.1.9.

3.1.4

line spread function (LSF) of the sampling aperture of a sampled imaging system

$L_{ap}(u)$

variation in sampled intensity, or signal, for a single sampling aperture or line of the sampling array, as a narrow line object is traversed across that aperture, or line and adjacent apertures or lines

NOTE 1 The direction of traverse is perpendicular to the length of the narrow line object and in the case of systems which sample over discrete lines, is also perpendicular to these lines.

NOTE 2 $L_{ap}(u)$ is a one-dimensional function of position u in the object plane, or equivalent position in the image.

3.1.5

optical transfer function (OTF) of a sampling aperture

$D_{ap}(r)$

Fourier transform of the line spread function, $L_{ap}(u)$, of the sampling aperture

$$D_{ap}(r) = \int L_{ap}(u) \cdot \exp(-i2\pi ur) du$$

where r is the spatial frequency

3.1.6

modulation transfer function (MTF) of a sampling aperture

$T_{ap}(r)$

modulus of $D_{ap}(r)$

3.1.7

reconstruction function

function used to convert the output from each sampled point, aperture or line, to an intensity distribution in the image

NOTE The reconstruction function has an OTF and MTF associated with it denoted by $D_{rf}(r)$ and $T_{rf}(r)$ respectively.

3.1.8

MTF of a sampled imaging system

$T_{sys}(r)$

product of the aperture MTF, $T_{ap}(r)$, and the MTF of the reconstruction function, $T_{rf}(r)$, with the MTF of any additional input device (e.g. a lens) and output device (e.g. a CRT monitor) which are regarded as part of the imaging system

NOTE When quoting a value for T_{sys} it should be made clear what constitutes the system. The system could, for example, be just a detector array and associated drive/output electronics, or could be a complete digital camera and CRT display.

3.1.9**Fourier transform of the image of a narrow slit produced by the imaging system** $F_{\text{img}}(r)$

$$F_{\text{img}}(r) = \int L_{\text{img}}(u) \cdot \exp(-i2\pi ur) du$$

where the line spread function of the system, $L_{\text{img}}(u)$, is the variation in sampled intensity, or signal, across the image of a narrow slit object generated by the complete system

NOTE $L_{\text{img}}(u)$ is different for different positions of the slit object relative to the sampling array.

3.1.10**aliasing function of a sampled imaging system** $A_{\text{F, sys}}(r)$

half the difference between the highest and lowest value of $|F_{\text{img}}(r)|$ [i.e. the modulus of $F_{\text{img}}(r)$] as the image of the MTF test slit is moved over a distance equal to, or greater than, one period of the sampling array

$$A_{\text{F, sys}}(r) = \frac{|F_{\text{img}}(r)|_{\text{max}} - |F_{\text{img}}(r)|_{\text{min}}}{2}$$

NOTE 1 It is the limiting value of this difference as the width of the test slit approaches zero (i.e. its Fourier transform approaches unity).

NOTE 2 $A_{\text{F, sys}}(r)$ is a measure of the degree to which the system will respond to spatial frequencies higher than the Nyquist frequency and as a result generate spurious low frequencies in the image.

3.1.11**aliasing ratio of a sampled imaging system** $A_{\text{R, sys}}(r)$

ratio $A_{\text{F, sys}}(r)/|F_{\text{img}}(r)|_{\text{av}}$, where $|F_{\text{img}}(r)|_{\text{av}}$ is the average of the highest and lowest value of $|F_{\text{img}}(r)|$ as the image of the MTF test slit is moved over a distance equal to, or greater than, one period of the sampling array

NOTE $A_{\text{R, sys}}(r)$ can be considered as a measure of the noise/signal ratio where $A_{\text{F, sys}}(r)$ is a measure of the noise component and $|F_{\text{img}}(r)|_{\text{av}}$ as a measure of the signal.

3.1.12**MTF of an imaging pick-up subsystem** $T_{\text{imp}}(r)$

product of the aperture MTF, $T_{\text{ap}}(r)$, with the MTF of the lens, $T_{\text{lens}}(r)$, where the MTF of the lens includes the effect of any optical anti-aliasing filters that are part of the system and which form the image on the sampling array

3.1.13**aliasing potential of a sampled imaging system** $A_{\text{P, imp}}$

ratio of the area under the imaging pick-up MTF, $T_{\text{imp}}(r)$, from $r = 0,5$ to $r = 1$, to the area under the same curve from $r = 0$ to $r = 0,5$, where the spatial frequency (r) is normalized so that $1/a$ becomes unity

ISO 15529:2010(E)**3.2 Symbols**

See Table 1.

Table 1 — Symbols used

Symbol	Parameter	Units
$A_{F, \text{sys}}(r)$	Aliasing function associated with the complete imaging system	1
$A_{P, \text{imp}}$	Aliasing potential associated with the imaging subsystem	1
$A_{R, \text{sys}}(r)$	Aliasing ratio associated with the complete imaging system	1
a	Sampling period	mm, mrad, degrees
$1/(2a)$	Nyquist spatial frequency limit	mm^{-1} , mrad^{-1} , degree^{-1}
$D_{\text{ap}}(r)$	Optical transfer function of a sampling aperture	1
$D_{\text{lens}}(r)$	Optical transfer function of the optical system including any anti-aliasing filters	1
$D_{\text{rf}}(r)$	Optical transfer function of the reconstruction function	1
$F_{\text{av}}(r)$	Fourier transform of $L_{\text{av}}(u)$	1
$F_{\text{img}}(r)$	Fourier transform of the final image of the slit object	1
$F_{\text{in}}(r)$	Fourier transform of $L_{\text{in}}(u)$	1
$F_{\text{slit}}(r)$	Fourier transform of the slit object	1
$L_{\text{ap}}(u)$	Line spread function of a sampling aperture	1
$L_{\text{av}}(u)$	Line spread function obtained by averaging the LSF associated with different positions of the slit object relative to the sampling array	1
$L_{\text{img}}(u)$	Line spread function associated with the complete imaging system	1
$L_{\text{in}}(u)$	Line spread function of the combination of slit object, optical system including any anti-aliasing filters and sampling aperture	1
r	Spatial frequency	mm^{-1} , mrad^{-1} , degree^{-1}
$T_{\text{ap}}(r)$	Modulation transfer function of a sampling aperture	1
$T_{\text{imp}}(r)$	Modulation transfer function of an imaging pick-up subsystem	1
$T_{\text{lens}}(r)$	Modulation transfer function of the optical system including any anti-aliasing filters	1
$T_{\text{rf}}(r)$	Modulation transfer function of the reconstruction function	1
$T_{\text{sys}}(r)$	Modulation transfer function of a sampled imaging system	1
u	Local image field coordinate	mm, mrad, degrees

4 Theoretical relationships

4.1 Fourier transform of the image of a (static) slit object

4.1.1 General case

The stages of image formation in a generalized sampled imaging system are illustrated in Figure 1. The values of the relevant parameters used in this International Standard are specified in Clause 3.

Key

- 1 slit object $F_{\text{slt}}(r)$
- 2 lens OTF, $D_{\text{lens}}(r)/\text{MTF}$, $T_{\text{lens}}(r)$
- 3 sampling apertures OTF, $D_{\text{ap}}(r)/\text{MTF}$, $T_{\text{ap}}(r)$
- 4 reconstruction function OTF, $D_{\text{rf}}(r)/\text{MTF}$, $T_{\text{rf}}(r)$

Figure 1 — Image formation by a sampled imaging system

For a sampled imaging system we have:

$$F_{\text{img}}(r) = \left(\sum_k \left\{ F_{\text{in}}(r - k/a) \cdot \exp[i2\pi\phi(k/a)] \right\} \right) \cdot D_{\text{rf}}(r) \quad (1)$$

where

$$F_{\text{in}}(r) = F_{\text{slt}}(r) \cdot D_{\text{lens}}(r) \cdot D_{\text{ap}}(r); \quad (2)$$

k is an integer (i.e. $k = 0, 1, 2, 3, \dots$);

ϕ is a phase term describing the position of the slit relative to the sampling array.

NOTE More information on the mathematical relationships involved in imaging with sampled systems can be found in References [2] and [3], and in most textbooks dealing with Fourier transform methods.

4.1.2 Special cases

4.1.2.1 General

The relationships listed in this clause are given without derivation (a brief explanation of their derivation can be found in Annex A).

4.1.2.2 Cut-off spatial frequency of $|F_{\text{in}}(r)|$ is less than or equal to the Nyquist frequency $1/(2a)$

For this condition and for spatial frequencies less than the Nyquist frequency, the system behaves as a non-sampled system and we have:

$$|F_{\text{img}}(r)| = |F_{\text{in}}(r)| \cdot T_{\text{rf}}(r) \quad (3)$$
